Introduction

Description of the system

The project that we are implementing is called Car-Sharing Service, with the help of which users can reserve the electrical car and use it. The service is based on web application with one target of people:

- users

Users must provide information about themselves, including their credentials and payment information in order to register an account in this system, and access it.

Users can locate available electrical cars nearby or in the certain area. Also users can see current battery fullness of each car.

After selecting the car, user can reserve it for up to one hour. When a user reaches the reserved car, system allows the user to unlock the car. As soon as the engine ignites, users can see current charges through the screen in the car.

User can leave the car for a short period of time without missing the car reservation. When the user tells the system that he doesn't need the car no more, it stops charging the user. At this point the car can't be controlled by the user no more and it becomes available for other users.

System, in order to restrain the behaviour of users, and to encourage virtuous behaviours of users, will carry out some reward and punishment features.

Actual system

Sometime ago the car sharing companies used the system according to which the car identifies users only by their membership cards. Such system forces users to have membership cards, that must be ordered and collected.

The system we suggest reduces the necessity to have such cards, but lets the users to use the car via web application, where only registration is needed.

During registration user provides all the necessary information, including payment credentials.

Goals

- [G1] Registered user can access the system.
- [G2] Registered users can locate all unoccupied electric cars parked nearby or within the specific area.
- [G3] Registered users can see the information about battery fullness of each unoccupied electrical car.
- [G4] User can reserve available electric car.
- [G5] User can access the reserved car.
- [G6] User can park the car for later usage without missing the "occupied" status.
- [G7] User is notified about current driving charges.
- [G8] User is encouraged to use the service properly.
- [G8.1] User has a 10% discount when he picks at least 2 more passenger onto the car.
- [G8.2] User has a 20% discount on the ride if he left the car with no more than 50% battery empty.
- [G8.3] User has a 30% discount on the ride if he left the car on the special parking area with the power grid station and plugged car to it.

Domain properties

We suppose that these properties hold in the analysed world :

- All electric cars have GPS navigators.
- All electric cars have battery charge sensors.
- Users drive accurately, without a car damage.
- Car has an inner OS, that process information from sensors(cameras, engine state, battery fulness), starts/kills engine, locks/unlocks doors, display information on the screen.
- Special charging parking areas are defined in advance
- GPS navigators state the right positions of users and cars
- Company has workers that charges cars that are left uncharged and far from charging station and park them in a convenient place
- Payments involves external bank services
- Car location and routing to them is provided by external web-services
- Car can only be charged on the special parking area

Application domain

Car-sharing system is able to be implemented in the area where

- Transportation internet is busy.
- Emissions serious.
- Public transportation infrastructures are imperfect.

The applicable group:

- People who is a environmentalist.
- People who use car occasionally.
- People who without private car.

Glossary

- User: He/She is a client of car-sharing service who always sends requests to system. He is able to register and access the system, reserve and use available cars. While registering he/she should insert the following information:
 - Name and Surname
 - Payment credentials
 - Phone number
 - Username
 - Password
- In order to search and reserve the car, user must provide his/her position or coordinates of specific area. Position can be acquire by the system automatically via GPS.
- Passengers: User is allowed to pick up people to join the trip.

- If the system detects the user took at least two other passengers onto the car, the system applies a discount of 10% on the last ride.
- passengers should be detected by device (e.g. face image capture)
- Electric car: Car, that uses electrical power to drive.
- Available car: Car that can be reserved by any registered users.
- Occupied car: Car from the moment user starts the engine to the time he ends the trip.
- Unoccupied car: It is same as “Available car”
- Reserved car: Car requested by the user. Reservation status lasts for 1 hour. Afterwards car becomes Available and user is charged with 1 Euro.
- Trip: The period from the moment when user starts to use the car until the end of the ride.
- Specific area: are that is specified by the user within which the system searches for unoccupied cars. This area is 1km^2 .
- Special parking areas: These are the areas where car can be parked and plugged into the power grid station for recharging.
- Position/Location: GPS coordinates
- System/Background System: Platform that is being implemented. It’s responsible to respond to the requests or commands from users.
- Background System: the same as the “System”, to distinguish the systems specified in the “Car’s OS” paragraph.
- Car’s inner OS: It is an car’s embedded operating system that
 - provides information to background system
 - responds to requests from background system
 - can interact with a screen that notifies the user about the current charges
 - acquires information from sensors of the car
- “Unlock” button: button in the web application that can unlock the door of car. It is also physically implemented inside the car. Can be used only if the system states that the user is nearby the reserved car.
- “Start/kill Engine” button: This button can ignite or kill the engine. Implemented physically inside the car.
- “End The Trip” button: Button in the web application that must be pressed when user finishes the trip. System stops charging the user.
- Power grid station: place, where user is able to recharge the car.

Constrains

Regulatory policies

The System must keep the payment information of users confidentially.
The System must ask users permission to use his/her GPS coordinates.

Hardware limitations

User’s devices
3G/4G connection
GPS
Space for app package

Car's OS

- Internet connect to background system
- With a screen (show current charge)
- Basic configurations as a normal car
- GPS

Software limitation

- Hold three version:IOS,Android,webpage
- User is unable to login in one more devices at the same time
- The application with sufficient reaction speed to user's request
- System can hold one reservation in same status when user change

Parallel operation

The server supports parallel operations from different users.

Proposed system

The architecture(Figure.2) of Car-Sharing based on common API and MVC pattern, we just have one server application,web application.

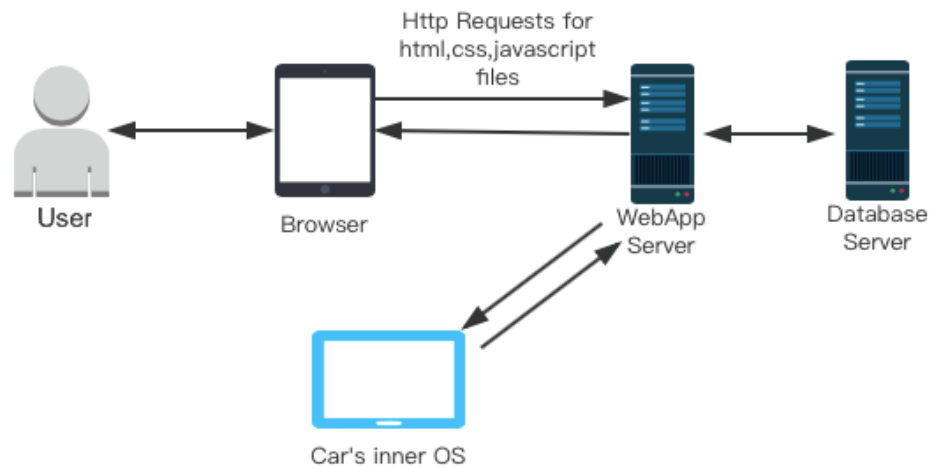

Figure 2: Architecture

Identifying stakeholders

Here are 3 stakeholders as follows. The main purpose of this system is that to provide environmental and social benefits to the communities in which it operates.

Environment:

- It reduces the number of vehicles driven in our cities.
- It eases the burden on the public road infrastructure.
- It reduces greenhouse gas emissions and other pollutants.
- It reduces the cost of transportation for the local populace.

Government:

Car-sharing is a reliable and flexible alternative to car ownership and is becoming an increasingly important factor in the transportation equation, aiming to assume the role of a new service of public interest as part of a sustainable transportation network.

Residents:

car-sharing implements the efficient, convenient and affordable way of renting a car. It simplifies the artificial mechanism of renting a car.

Reference documents

- Specification Document: Assignments 2016-2017.pdf
- IEEE Std 830-1998 IEEE Recommended Practice for Software Requirements Specifications.
- Examples documents: RASD sample from Oct. 20 lecture.pdf

Actors identifying

Here is just one actor in our system: user

- User: He is a client of car-sharing service who always send requests to system. He is able to register by credentials and payment information and access the system, reserve and use available cars as well. Besides, He should to pay rent to Car-sharing company. According to the behaviors of user, system provides users discounts or charge more for users.

Requirements

Functional requirements

In the “Domain assumptions” paragraph we defined expectations from the analyzed world. Having this information and stated goals we can derive functional requirements to the implemented System.

[G1] Registered user can access the system:

System must provide a user with registration or sign in procedure.

[G2] Registered users can locate all unoccupied electric cars parked nearby or within the specific area:

The system must acquire and provide to the user the information about location of all unoccupied cars within the certain area

The system must notify user to turn on the GPS on the smartphone while locating nearby cars.

The system must search available cars within the coordinates provided by user.

[G3] Registered users can see the information about battery fullness of each unoccupied electrical car.

The system must acquire and provide to the user information about car’s battery fullness

[G4] User can reserve available electric car.

System must allow the registered user to reserve 1 chosen unoccupied electric car for up to 1 hour.

When 1 hour after reservation is up, the system must state that the car is available and charge the user for 1 euro.

[G5] User can access the reserved car

System must provide the “lock/unlock” feature to the user when he/she reaches the reserved car

“Lock/unlock” feature can only be used if the user is close to the reserved car.

System must stop counting the reservation time and state that the car occupied after the user starts the engine for the first time

[G6] User can park the car for later usage without missing the “occupied” status.

System must provide the “end of the trip” button when the user decides to quit using the car.

System must charge user less, when the engine is turned off.

System must state that the car is available if the engine is suspended for more than 1 hour.

System must warn the user, when the time of the car left suspended is going to expire.

[G7] User is notified about current driving charges.

System must display charging information on the screen in the car.

[G8] User is encouraged to use the service properly

[G8.1] User has a 10% discount when he picks at least 2 more passenger onto the car. system must provide 10% discount for the time while it gets information that there are 2 more passengers in the car

[G8.2] User has a 20% discount on the ride if he left the car with no more than 50% battery empty.

System must provide 20% discount on the whole ride \Leftrightarrow user states that the car is no more needed + battery’s fullness is not less than 50% full

[G8.3] User has a 30% discount on the ride if he left the car on the special parking area with the power grid station and plugged car to it.
System must provide 30% discount on the whole ride \Leftrightarrow user states that the car is no more needed + the car is on the special parking area + car's battery is charging

Global requirement for the System:

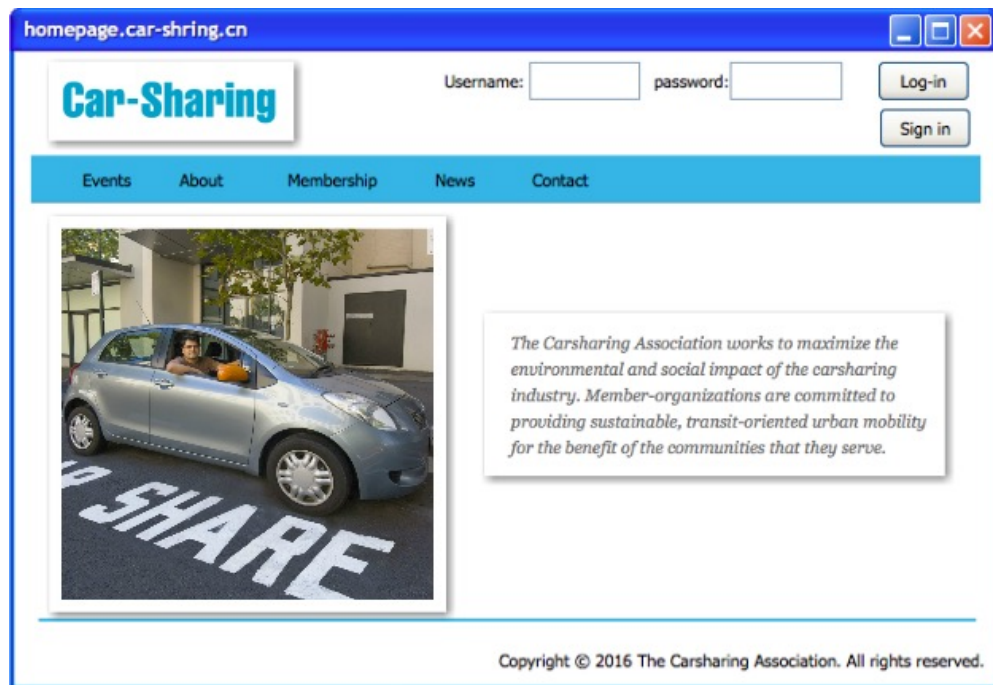

System must be able to communicate with car's inner OS to acquire processed information from car's sensors, send signals to lock/unlock door, to display information on the screen.

Documentation

These documents as follows, will to be used in our project in the way to do in a fewer time the best work as possible:

RASD: The Requirements analysis and specification document (RASD) contains the description of the scenarios, the use cases that describe them, and the models describing requirements and specification for the problem under consideration.

DD: The Design document (DD) must contain a functional description of the system, and any other view you find useful to provide.

ITPD: The Integration Test Plan Document (ITPD) aims at describing how you plan to accomplish the integration test. This document is supposed to be written before the integration test really happens.

PP: The Project Plan (PP) aims at defining a planning for your project.

Scenario identifying

Here some possible scenarios of usage of this application.

Scenario 1

Melissa needs to get to the job, which is on the other side of Milano. But due to the protests on Friday, metro is closed. Melissa new about it in advance, so she decided to use the Car-Sharing system. She registered and reserved the nearest electric car in the morning and reached the job.

Scenario 2

Jack is the tourist and he decides to watch all the main places of Milano. He decides to use the Car-Sharing system. He finishes the registration via smartphone, reserves the nearest car and drives it to the different destinations. When he reaches the destination he leaves the car suspended and locked to watch the attractions. When he returns he unlocks the car and drive it to another places.

Scenario 3

Nicola lives far from the city and needs to get his son from school, but his car is broken. He already has an account in the Car-Sharing system and reserves the electric car on the specific area that is close to the train station. He reaches this station by train and drives to the son's school be the reserved car. When he picks his son he drives back home and leaves it nearby his house with the 85% battery empty. Nicola is charged 30% more.

Scenario 4

Kate decides to take a ride home by the electric car after meeting her friend in the cafe. She reserved the car nearby and continued to talk to her friend. Suddenly she realizes that the time of reservation is going to expire. She misses the reservation time and is charged by 1 Euro.

Scenario 5

Luci's car is broken. In the morning she always drive her children Peggy and Steve to the school and then she drives to her job. She reserved the electric car not far from her house with 100% battery fulness. When family gets to the car it captures that there are 3 people in the car and system starts to charge Luci 10% less. After she drove Peggy and Steve to the school, system stops the discount charging. After Luci drove to her job, the battery was more than 50% full. The total price for the ride is the sum of the discount time charging, when she was driving with her kids and the time charging without discount, when she was driving alone. Plus she gets 10% discount on the total price, because car is left with more than 50% full battery.

Scenario 6

Caroline has reserved the car electric and want to go to the bank. Luckily bank is situated near the special parking area. When she gets there, she parks on that area and plug the car to the power station. Caroline gets 30% discount on the ride.

UML models

Use case diagram

Figure 3: use case diagram

Use case description

User registers

Name: User registers

Actor: User

Entry condition: there is no entry condition

Flow of events:

- User go to the System website.
- User clicks on the registration button.
- The system redirects the user to a form where he has to furnish the following information:

- Username
- Password
- Drive license
- E-mail address
- Telephone number
- Payment and credentials

-User press "register" button. System sends the e-mail confirmation letter to the stated e-mail address.

-User goes to the e-mail and press on confirmation link in the confirmation letter.

Exit condition: The system notifies the user registered successfully, and redirects the user to login page.

Exceptions: The user inputs an invalid payment information (eg. wrong cvv of credit card), system will notify the user that he should check his payment information and input again. Until user provides information all valid, system redirects user to login page.

User log-in

Name : User log-in

Actors : User

Entry condition : The user has already registered successfully..

Flow of events:

- The user inputs his username and password.
- The user click on log-in button.

Exit condition: The user is successfully access into home page, and he can see both his location and all available cars from the e-map of app.

Exceptions: The user inputs incorrect password, system prevent user from accessing into reservation page, and notifies user that the password or username is incorrect. Besides, system allows user to input username and password again.

User choose a car

Name : User choose a car

Actors : User

Entry condition : The user must already logged in successfully

Flow of events:

- The user location himself position or inputs an address of a specific area.
- The user search all unoccupied electric cars parked nearby or inputs a specific area.
- The user click the icon of one car.

Exit condition:

-The location of all unoccupied cars nearby or within a specific area can be shown on user's devices.

-The user is able to see the detail information of any available car when user click the icon of one available car.

Exceptions: The user didn't turn on his GPS function in his devices, system can not acquire the

location of user, which leads to system unsuccessfully provides information for user. System would notify him to turn on it and try again.

User reserve a car Name : User reserve a car

Actors : User

Entry condition : The user has already clicked the icon of one of the cars he chose.

Flow of events:

- The user clicks "Reserve" button.

- The user clicks "Yes" button, when system asks him whether he is sure to reserve this car.

Exit condition:

- System directs the user to the page where system timing the time of one hour for user's reservation.

- When user is nearby the reserved car, the "unlock the car" button is activated

Exceptions:

- The user just clicks into the page about details of the car, but he didn't click the "Reserve" button. So his reservation is invalid.

- After one hour the user still doesn't appear nearby the car, "unlock the car" button cannot be activated. His reservation turns to invalid. Here one euro is also charged by system.

User use the car

Name : User use the car

Actors : User

Entry condition : The "unlock the car" button has been activated

Flow of events:

- The user clicks "Unlock" button via app then gets on the car.

- When user gets off the car, clicks "Lock car" button.

- The user clicks "End the trip" to stop current trip, system stops charging.

Exit condition:

- System unlocks the car when user clicks "Unlock car" button, and the screen of the car becomes on where user can check current charge.

- System locks the car when user clicks "Lock car" button.

- System automatically locks the car and stops charging when user clicks "End the trip" button.

- User can see details about the bill for this trip from his device.

Exceptions: There are no exceptions for this use case.

User pay the bill

Name : User pay the bill

Actors : User

Entry condition : System has already provided bill information to user.

Flow of events:

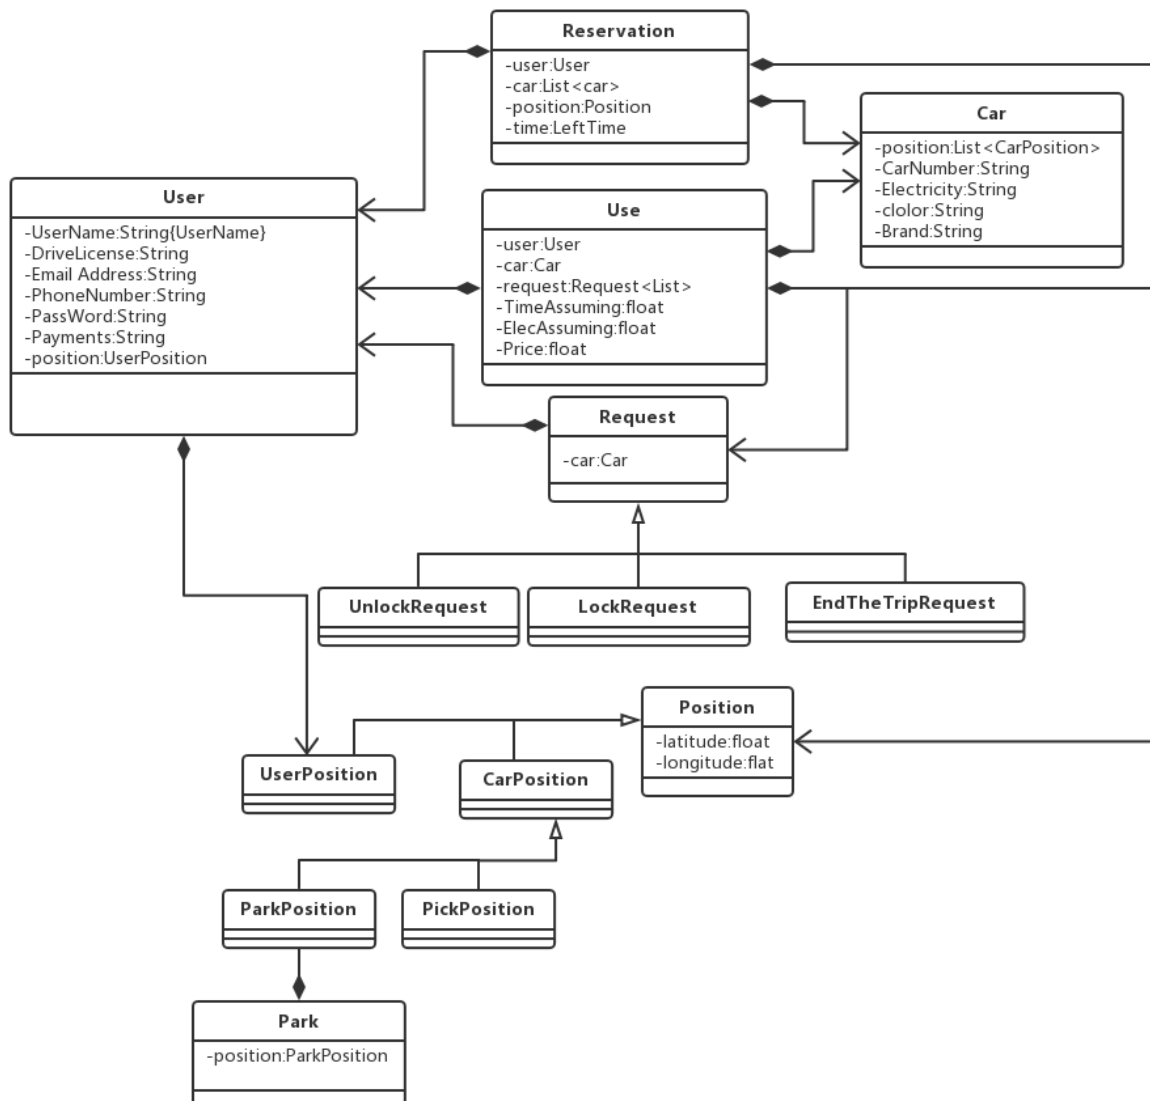

- The user chooses a way to pay the bill.

- The user inputs his code of the payment he chooses.

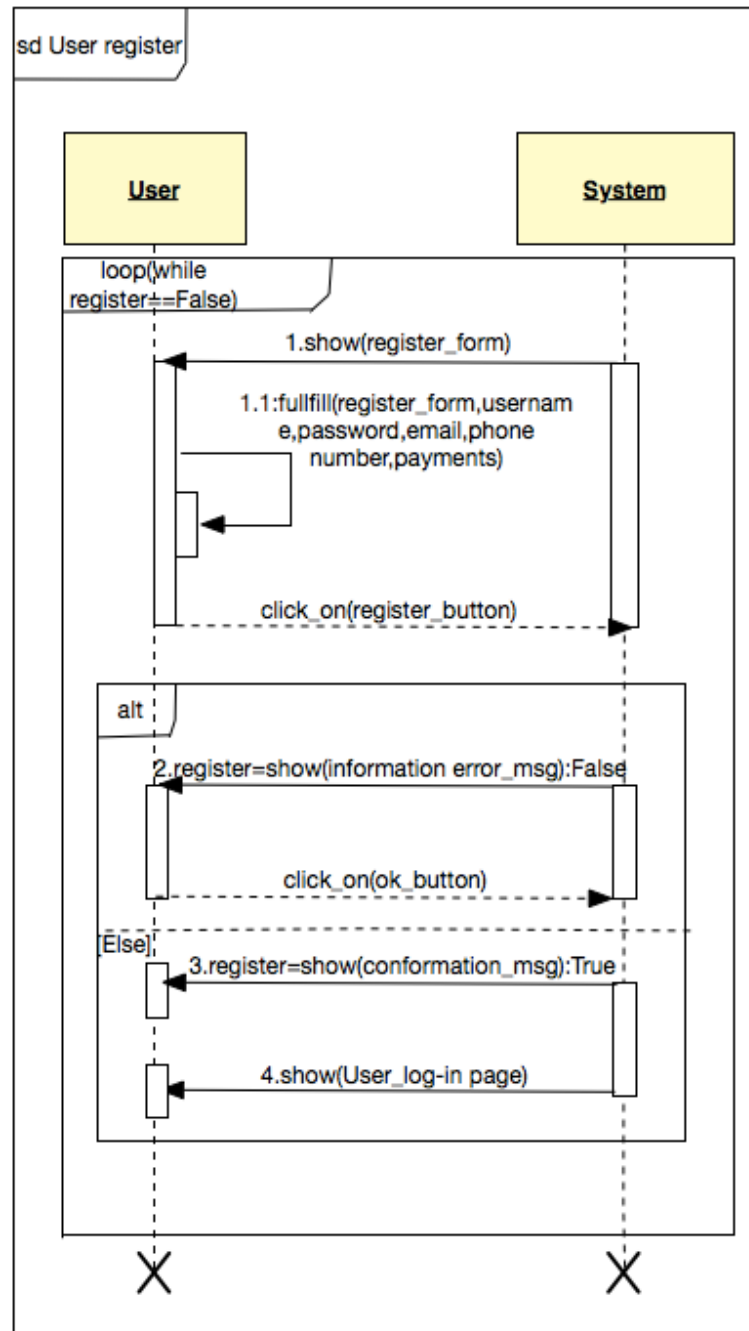

Exit condition: The system redirects the user to a success-paid page, where the system notifies user has already successfully paid this trip.

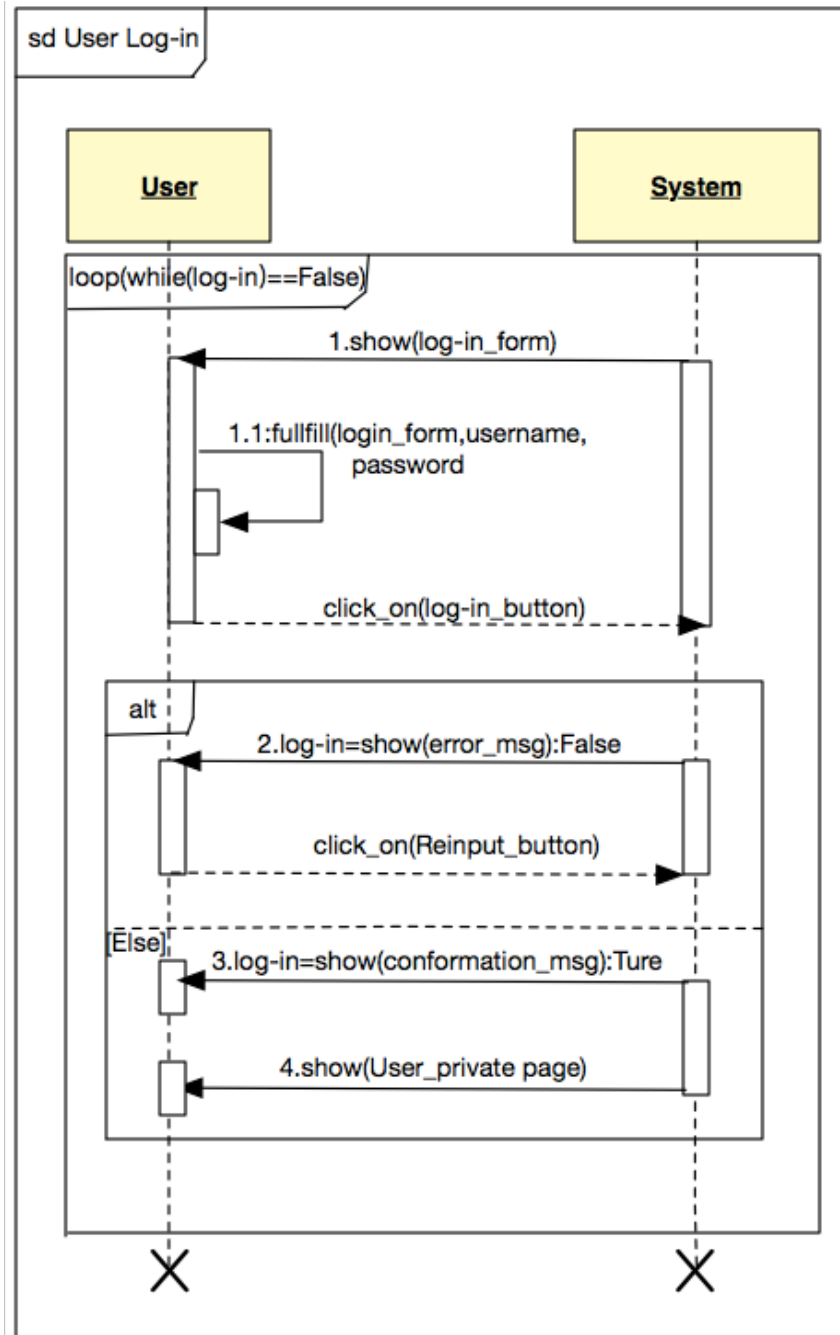

Exceptions: The user inputs an incorrect code, in that case, system redirects the user to a unsuccessful-paid page, and notifies user should input code again. Until user inputs correct code, system redirects the user to a success-paid page.

Future development

We plan to implement more versions(IOS,Android) for smartphone app in the future work.

Used tools

The tools we used to create this RASD document are:

- ProcessOn: for uml models
- Github: for version controller
- Pencil: for mockup
- OmniGaffle: for sequence diagram
- Gmail: for check other's modified documents
- Alloy Analyzer 4.2: to prove the consistency of our model.
